BY JACARE SUGGESTING

They found, at the height of the current heatwave, hundreds of millions of people of all ages using their expensive computers and cell phones around the world. Reports of the number of people using computers in Africa, Asia and the European Union have skyrocketed, and the ones who got the information from the internet have multiplied.

The data is in a database that a South African professor of electronic mathematics named Kip Miyachi has created at Zavvi University (ZAN) in Johannesburg, Africa to match the information from their computers.

Miyachi says the average person in sub-Saharan Africa spends only 24 minutes per day using their computers. This is considerably higher than the 30 minutes I spent on the internet in the 1970s and 80s when people used to spend 24 minutes per day using their computers.

That is why it's fascinating to see that 1 in 9 people who don't use their computers today have mobile phones.

Miyachi said that the problems with mobile phones include the frequent use of motion control, noise control, distraction etc, various identification issues and the opening of window bars.

Phone technology itself is a challenge that has had some difficulty to overcome. He said to enhance these in the current scenario, computer development must be integrated and systems development should be simplified.

A poorly implemented system based on pornography does not represent the idea of a thriving internet, and we are not seeing it anytime soon.

Perhaps we are being led to believe that consumers will in turn have a solution to this as of next year.

It's extremely unlikely. This is as a message to the world's overburdened public and the authorities is relying on parliament to vote on it before the census.
